ABSTRACT

The edible freshwater bivalves identified in Cagayan River were : *Batissa childreni*, *Corbicula manilensis* and *Psammotaea virescens*. *Corbicula manilensis* was the most abundant species collected. High density and bigger sized bivalves were collected in the months of May, which was the peak season. A high density of *Batissa childreni* was noted as the temperature of water was low. Total hardness and organic content significantly influenced the density of *Corbicula manilensis* and *Psammotaea virescens*. Lesser density of *Corbicula manilensis* resulted as the total hardness decreased while high density of *Psammotaea virescens* was noted as the organic content of the substrate increased. Relative abundance was greatly affected by the total water hardness. A positive correlation existed between relative abundance of *Batissa childreni* and total hardness while a negative correlation existed between relative abundance of *Corbicula manilensis* and total hardness. Shell size of *Corbicula manilensis* was bigger as the total hardness increased and bigger sized *Psammotaea virescens* was noted as the organic content of the substrate increased. No predictor variables were significantly correlated with relative abundance of *Psammotaea virescens* and the shell size of *Batissa childreni*.
